## Report:

## REPORT OF THE ESRF-CH1017 EXPERIMENT

## 1- INTRODUCTION

This experiment was a contribution to a program offering an environmentally friendly alternative to the zinc and magnesium protection conversion process. The project number CH 1017 , proposed to determine the crystallographic structures of the corrosion inhibitors with general formula $\mathrm{M}\left(\left(\mathrm{CnH}_{2 \mathrm{n}-1}\right) \mathrm{O}_{2}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{\mathrm{x}}$ with n $\geq 10$ (code MCn with $\mathrm{M}=\mathrm{Zn}, \mathrm{Mg}$ ) using ab-initio methods of resolution. We measured also same well structured mixing compound as $\mathrm{ZnCn}-\mathrm{ZnCn}$ '. Among the nine samples measured (see the table after), three new structures have been fully determined. Some results are presented in the following.

## 2- EXPERIMENTAL

X-ray powder diffraction data were collected by using the synchrotron radiation at the Europeen Synchrotron Radiation Facilities (ESRF), on the very high resolution powder diffractometer installed on the beam line ID31. A primary double crystal monochromator $\operatorname{Si}(111)$ is used for selecting the wave length. The detection is ensured by nine consecutive crystals $\mathrm{Ge}(111)$ analyser. The sample constituted of a fine powder is introduced in a Lindeman tube ( $\Phi=1 \mathrm{~mm}$ ). The sample was contained in spinning on the axis of the diffractometer. The capillary was translated along the axis to give a fresh region of sample every 15 mn to avoid radiation damage. Data were recorded by using a wave length of $0.851243(4) \AA$, at 100 K with an interval of $0.003^{\circ}$ and a total counting time of 2 h .

## 3- CRYSTALLOGRAPHIC RESULTS

## 3-1- Mixed compounds

## $\mathbf{Z n}\left(\mathbf{C}_{\mathbf{1 0}} \mathbf{H}_{\mathbf{1 9}} \mathbf{O}_{\mathbf{2}}\right)\left(\mathbf{C}_{\mathbf{1 4}} \mathbf{H}_{\mathbf{2 7}} \mathbf{O}_{\mathbf{2}}\right)(\mathrm{ZnC10C14})$

The diffraction pattern of the mixed compound $\mathrm{ZnC10} \mathrm{C} 14$ could be indexed in a triclinic lattice P1 with the parameters: $\mathrm{a}=4.311$ (1) $\AA, \mathrm{b}=4.997(1) \AA, \mathrm{c}=28.999(1) \AA, \alpha=94.80(1)^{\circ}, \beta=93.16(1)^{\circ}=$ and $\gamma=$ $\left.64.57(1)^{\circ}\right)$. Rietveld refinement is presented on figure $1\left(\mathrm{Rp}=15.1, \mathrm{Rwp}=21.9\right.$, Chi2 $=26.8, \mathrm{R}_{\mathrm{B}}=14.8, \mathrm{R}_{\mathrm{F}}$ $=12.7$ ). Structural model showing the structure with adjacent $\mathrm{ZnC10}$ and $\mathrm{ZnC1} 4$ slabs is shown on Figure 1 . Atomic coordinates for $\mathrm{ZnC10C1} 4$ are reported in Table 1

Figure1 : Rietveld refinement for $\mathrm{Zn}(\mathrm{C} 10-\mathrm{C} 14)$

Figure 2: projection along [100] of the structure of $\mathrm{Zn}\left(\mathrm{C}_{10} \mathrm{H}_{19} \mathrm{O}_{2}\right)\left(\mathrm{C}_{14} \mathrm{H}_{27} \mathrm{O}_{2}\right)$

Table1 : Final fractional coordinates for non-hydrogen atoms for $\mathrm{Zn}\left(\mathrm{C}_{10} \mathrm{H}_{19} \mathrm{O}_{2}\right)\left(\mathrm{C}_{14} \mathrm{H}_{27} \mathrm{O}_{2}\right)$.

$\mathbf{M g}\left(\mathbf{C}_{\mathbf{1 0}} \mathbf{H}_{\mathbf{1 9}} \mathbf{0}_{\mathbf{2}}\right)_{\mathbf{2}}\left(\mathbf{H}_{\mathbf{2}} \mathrm{O}\right)_{\mathbf{3}}(\mathrm{MgC10})$
Magnesium carboxylates contain water molecules. The structure of $\mathrm{Mg}\left(\mathrm{C}_{10} \mathrm{H}_{19} \mathrm{O}_{2}\right)_{2}\left(\mathrm{H}_{2} \mathrm{O}\right)_{3}$ determined from synchrotron data is similar to that of heptanoate equivalent. No evidence for existence of polytypes is observed. Rietveld refinement (see Figure 5) of the powder pattern leads to satisfactory R factors $\left(\mathrm{R}_{\mathrm{B}}=7.7 \%\right.$, $\mathrm{R}_{\mathrm{wp}}=6.3 \%, \chi^{2}=2.71$ ). The structure is presented in Figure 6. The magnesium atoms are in a octahedron constituted by three oxygen atoms coming from carboxylate groups and by three oxygen atoms coming from water molecules. The layer thus consists of two half-layers connected by hydrogen bonds.

## 4- CONCLUSION

At present time we have established structural models for the compounds $\mathrm{ZnC10C14}, \mathrm{ZnC10C16}$ and MgCl 10 . The indexation of the remaining pattern is in progress. Nevertheless, we have to emphasis that some patterns are relatively difficult to analyze. Indeed, some apparent 'pure' pattern can in fact be due to melt of polytypes with very narrow lattices. This is probably due to the various ways for stacking these lamellar structures. An other crucial problem in this kind of compound is the preferred orientation. It seems it remains relatively high although the facts the compound were measured in capillaries.
The results have been presented to EPDIC-10 in geneva (Suisse) [1] and to MATERIAUX-2006 in Dijon (France) [2].
